# **Algorithms**

Part 3: Time Complexity Basics
Constant, Linear, and Quadratic Time

Notes for CSC 100 - The Beauty and Joy of Computing The University of North Carolina at Greensboro

### Reminders

### Blown to Bits:

Chapter 3 on-line discussion contribute by Wednesday!

### Homework:

Homework 2 due in one week: Wed., Oct. 1

On the horizon: Midterm Wednesday, Oct. 8

### **Constant time**

We say a script (or part of a script or block definition) takes *constant time* if it is a constant (usually small) number of basic steps, regardless of input.

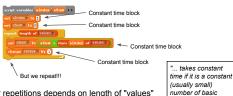

Question: Are all of these constant time?

## What about loops?

The number repetitions depends on length of "values"

So this is not constant time...

steps, regardless of input"

Constant time operations, repeated "length of input" times is linear time Mathematically: Constant time loop body is time "c"

Repeated "n" times where n is length of list Total time is then c\*n (that's a linear function!)

## **General iterator pattern**

On previous slide:

- Very important Time was expressed as a function of input size "Big Idea"!!!
- Could write time as T(n) = c\*n

In general:

We know how many times it repeats, and all basic blocks are constant time except perhaps our "do something..." block

- In general, if time for "do something..." block is T(n), then time for complete script with loop is n\*T(n)
- If "do something" is constant time, total time is c\*n (linear)
- It "do something" is linear time, total time is c\*n2 (quadratic)

### Two challenges

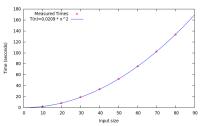

What's the time complexity?

# Plotting the Running Times Measured (using BYOB) and calculated running times for max pos:

Note: The straight line of this graph should remind you of linear function graphs from math class!

# **Plotting the Running Times**

Measured (using BYOB) and calculated running times for sort:

Note: The nice smooth parabola should be familiar to you from math class!

# **Another challenge**

The following predicate tests whether a list has any duplicates:

**Question**: What's the time complexity?

# **Predicting Program Times - Linear** Basic idea: Given time complexity and sample time(s) can estimate time on larger inputs Linear time: When input size doubles, time doubles When input size triples, time triples When input size goes up by a factor of 10, so does time Example: A linear time algorithm runs in 10 sec on input size 10,000 How long to run on input size 1,000,000? Answer: 1,000,000 / 10,000 = 100 times larger input Therefore 100 times larger time, or 10 \* 100 = 1,000 sec Or 1,000 / 60 = 16.667 minutes **Predicting Program Times - Quadratic** Basic idea: Given time complexity and sample time(s) can estimate time on larger inputs Quadratic time: When input size doubles (2x), time quadruples (4x) Input size goes up by a factor of 10, time goes up 10<sup>2</sup>=100 times Input size goes up k times, time goes up $k^2$ times Example: A quadratic time algorithm runs in 10 sec on input size 10,000 How long to run on input size 1,000,000? Answer: 1,000,000 / 10,000 = 100 times larger input Therefore $100^2 = 10,000$ times larger time, or 100,000 sec Or 100,000 / 60 = 1666.7 minutes (or 27.8 hours) **Predicting Program Times - Your Turn** Joe and Mary have created programs to analyze crime statistics, where the input is some data on each resident of a town Joe's algorithm is quadratic time Mary's algorithm is linear time Both algorithms take about 1 minute for a town of size 1000 Both would like to sell their program to the City of Greensboro (population 275,000)

<u>Problem</u>: Estimate how long each program would take to run for Greensboro

## **Summary**

- Algorithm "time complexity" is in basic steps
- Common complexities from this lecture, from fastest to slowest are constant, linear, and quadratic
  - o A single step, or sequence of constant-time blocks is constant time
  - A simple loop with constant time operations repeated is linear time
  - A loop containing a linear time loop is quadratic
- Speed depends on algorithm time complexity
  - o Constant time is great, but not many interesting things are constant time
  - Linear time is very goodQuadratic time is OK
- Given time complexity and one actual time, can estimate time for larger inputs
